

## The group of parenthesized braids

Patrick Dehornoy

Laboratoire de Mathématiques Nicolas Oresme  
Université de Caen, France

Topology Seminar, Tokyo University, May 7, 2015

- A group  $B_\bullet$  that extends both Artin's braid group  $B_\infty$  and Thompson's group  $F$ , occurring in various contexts:
  - ▶ “geometry group of an algebraic law”,
  - ▶ subgroup of M. Brin's braided Thompson group  $BV$ ,
  - ▶ quotient of a group of Greenberg–Sergiescu and Funar–Kapoudjian, ...
- Here: insist on similarity with  $B_\infty$  (use of **self-distributivity**)  
and connection with homeomorphisms of  $S^2 \setminus \text{Cantor}$ .

Plan:

- 1. Artin's braid group  $B_\infty$
- 2. Thompson's group  $F$
- 3. The parenthesized braid group  $B_\bullet$
- 4. The Artin representation of  $B_\bullet$

Plan:

- 1. Artin's braid group  $B_\infty$
- 2. Thompson's group  $F$
- 3. The parenthesized braid group  $B_\bullet$
- 4. The Artin representation of  $B_\bullet$

- Definition** (Artin): For  $n \geq 1$ , the **braid group**  $B_n$ 

$$= \{ \text{\textit{n-strand braid diagrams}} \} / \text{\textit{isotopy}}$$

$$= \pi_1(\text{\textit{configuration space of n points of } \mathbb{C} \text{ mod. action of } S_n})$$

$$= \text{\textit{MCG}}(D_n)$$

$$\uparrow$$

$$\{ \text{\textit{homeomorphisms of an n-punctured disk that fix } \partial D_n} \} / \text{\textit{isotopy}}$$

$$= \left\langle \sigma_1, \dots, \sigma_{n-1} \mid \begin{array}{l} \sigma_i \sigma_j = \sigma_j \sigma_i \quad \text{for } |i-j| \geq 2 \\ \sigma_i \sigma_j \sigma_i = \sigma_j \sigma_i \sigma_j \quad \text{for } |i-j| = 1 \end{array} \right\rangle.$$

$$\sigma_i : \begin{array}{c} | \quad \dots \quad | \quad \times \quad | \quad \dots \quad | \\ 1 \qquad \qquad \quad i \quad i+1 \qquad \qquad \quad n \end{array}$$

- Embedding  $B_n$  into  $B_{n+1}$ : add a trivial  $(n+1)$ st strand

- Then  $B_\infty := \varinjlim B_n = \langle \sigma_1, \sigma_2, \dots \mid \begin{array}{l} \sigma_i \sigma_j = \sigma_j \sigma_i \quad \text{for } |i-j| \geq 2 \\ \sigma_i \sigma_j \sigma_i = \sigma_j \sigma_i \sigma_j \quad \text{for } |i-j| = 1 \end{array} \rangle$ .

- Equivalently: Identify  $B_n$  with a subgroup of  $B_{n+1}$ , and put

$$B_\infty = \bigcup_n B_n.$$

- Viewing  $B_n$  as a group of (isotopy classes of) homeomorphisms of  $D_n$ :
  - action of  $B_n$  on the fundamental group of  $D_n$ , a free group of rank  $n$ .

- From there: homomorphism  $\rho$  from  $B_n$  to  $\text{Aut}(F_n)$ :

$$\rho(\sigma_i) : \begin{cases} x_i & \mapsto x_i x_{i+1} x_i^{-1}, \\ x_{i+1} & \mapsto x_i, \\ x_k & \mapsto x_k \text{ for } k \neq i, i+1. \end{cases}$$

- Theorem (Artin): *The homomorphism  $\rho$  is injective.*

Plan:

- 1. Artin's braid group  $B_\infty$
- 2. Thompson's group  $F$
- 3. The parenthesized braid group  $B_\bullet$
- 4. The Artin representation of  $B_\bullet$

- Definition (Richard Thompson, 1965):

$$F := \langle a_0, a_1, \dots \mid a_j a_i = a_i a_{j+1} \text{ for } j > i \rangle. \quad (*)$$

▶ occurs in the construction of a f.p. group with unsolvable word problem

- Fact: The group  $F$  is a group of right fractions for the monoid  $F^+$ .

↑  
the monoid presented by (\*)

- Fact: Every element of  $F$  has a unique expression of the form

$$a_0^{p_0} a_1^{p_1} \dots a_n^{p_n} a_n^{-q_n} \dots a_1^{-q_1} a_0^{-q_0}$$

such that  $((p_k \neq 0 \text{ and } q_k \neq 0) \text{ implies } (p_{k+1} \neq 0) \text{ or } (q_{k+1} \neq 0))$ .

- Fact: The group  $F$  is **finitely presented**:

▶ generated by  $a_0$  and  $a_1$ , since  $a_n = a_1^{a_0^n}$  for  $n \geq 2$ ;

▶ relations: " $a_2^{a_1} = a_3$ " and " $a_3^{a_1} = a_4$ ", that is,  $a_1^{a_0 a_1} = a_1^{a_0^2}$  and  $a_1^{a_0^2 a_1} = a_1^{a_0^3}$ .

- $F \simeq \{ \text{piecewise linear orientation preserving homeomorphisms of } [0, 1] \text{ with discontinuities of the derivative and slopes of the form } 2^k \}.$

also represented as

- An element of  $F$  = a pair of **dyadic decompositions** of  $[0, 1]$ :  
= a pair of finite **binary rooted trees**:

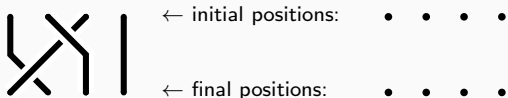

- Fact: *The center of  $F$  is trivial.*
  - ▶ Point: every homeomorphism commuting with  $x_1$  fixes  $1/2$ .
- Fact: *Commutators in  $F$  correspond to homeomorphisms with slope 1 near 0 and 1.*
  - ▶ Hence  $F/[F, F] \simeq \mathbb{Z} \oplus \mathbb{Z}$ .
- Proposition: *Every proper quotient of  $F$  is abelian.*
  - ▶ Point: Every normal subgroup contains all commutators.
- Theorem: *The subgroup  $[F, F]$  is **simple**.*
  - ▶ Point: A normal subgroup of  $[F, F]$  contains all commutators.
- Theorem (Brin–Squier, 1985): *The group  $F$  includes **no free subgroup** of rank  $\geq 2$ .*
  - ▶ In fact: Every non-abelian subgroup of  $F$  includes a copy of  $\mathbb{Z}^\infty$ .
  - ▶ Compare with:  $F^+$  includes a free monoid of rank 2.

- Question 1 (Gersten): Is  $F$  **automatic**? ( $F$  is not word hyperbolic)
  - ↑
  - ∃ finite state automaton computing a normal form for the elements
- Theorem (Guba 2005): *The **Dehn function** of  $F$  is quadratic.*
  - ↑
  - $\Phi(n) := \sup\{\text{area}(w) \mid \text{length}(w) = n \text{ and } w \text{ represents } 1 \text{ in } F\}$
- Question 2 (Geoghegan): Is  $F$  **amenable**?
  - ↑
  - ∃ left-invariant  $[0, 1]$ -measure on  $\mathfrak{B}(F)$
- Question 3: What is the **growth rate** of  $F^+$  and  $F$  w.r.t.  $\{a_0^{\pm 1}, a_1^{\pm 1}\}$ ?
  - ↑
  - $\sqrt[n]{a_n}$ , with  $a_n := \#\{\text{elements with length } n \text{ expression}\}$
- Theorem: - (i) (Burillo) *The growth rate of  $F^+$  is  $\frac{1}{2 \sin(\pi/14)} \approx 2.24\dots$*   
 - (ii) (Guba) *The growth rate of  $F$  lies between  $\frac{3+\sqrt{5}}{2} \approx 2.618\dots$  and 3.*

Plan:

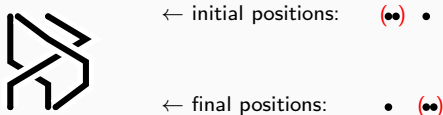

- 1. Artin's braid group  $B_\infty$
- 2. Thompson's group  $F$
- 3. The parenthesized braid group  $B_\bullet$
- 4. The Artin representation of  $B_\bullet$

- Ordinary braid diagrams:

- ▶ **one** elementary pattern: **crossing**  $\sigma_i$ :

- **Parenthesized** braid diagrams: (possibly) **non-equidistant** positions:

- ▶ **two** elementary patterns: **crossing**  $\sigma_i$  :
- grouping**  $a_i$  :

(and their inverses)

- More precisely:

- A typical parenthesized braid diagram:

- Connection with **binary trees**: positions correspond to **nodes** in a binary tree;
  - Enumerated starting from the root and descending the **right** branch.

$\sigma_i : \dots$    $\dots$  corresponds to

$a_i : \dots$    $\dots$  corresponds to

- For ordinary braid diagrams, only **one** completion:

corresponding to  $\bullet \bullet \bullet \mapsto \bullet \bullet \bullet \bullet$

- For **parenthesized** braid diagrams, **several** completions:

- ▶ index positions by **sequences of integers**  
(or, equivalently, **infinitesimals**)

- Parenthesized braid diagrams form a **groupoid** (small category with inverses):

$$\mathcal{B} := \{ \text{parenthesized braid diagrams} \} / \text{isotopy}.$$

- ▶ Two isotopy classes  $D, D'$  can be composed when  
the final positions of  $D$  coincide with the initial positions of  $D'$ .

- To make a **group**:

- ▶ Going from  $\coprod B_n$  (groupoid) to  $B_\infty$ : embed  $B_n$  into  $B_{n'}$  for  $n \leq n'$ .
- ▶ Going from  $\coprod B_t$  (groupoid) to a group: embed  $B_t$  into  $B_{t'}$  for  $t \subseteq t'$ .

$\uparrow$   
 the family of (isotopy classes) of diagrams with initial positions  $t$  (a binary tree)

- Definition: The group  $B_\bullet$  of **parenthesized braids** is  
 $\varinjlim \{ \text{parenthesized braid diagrams} \} / \text{isotopy}.$

- Proposition: A presentation of  $B_\bullet$  in terms of the generators  $a_i$  and  $\sigma_i$  is for  $x = \sigma$  or  $a$ :  $\sigma_i x_j = x_j \sigma_i$  and  $a_i x_{j-1} = x_j a_i$  for  $j \geq i + 2$ ,  
 $\sigma_i \sigma_j \sigma_i = \sigma_j \sigma_i \sigma_j$ ,  $\sigma_i \sigma_j a_i = a_j \sigma_i$ ,  $\sigma_j \sigma_i a_j = a_i \sigma_j$  for  $j = i + 1$ .

- ▶ **commutation** relations:

$$\sigma_i \sigma_j = \sigma_j \sigma_i \qquad \sigma_i a_j = a_j \sigma_i \qquad \text{for } j \geq i + 2$$

- ▶ **semi-commutation** relations (“Thompson” relations):

$$a_i \sigma_{j-1} = \sigma_j a_i \qquad a_i a_{j-1} = a_j a_i \qquad \text{for } j \geq i + 2$$

- ▶ **braid** relations:

$$\sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1} \qquad \sigma_i \sigma_{i+1} a_i = a_{i+1} \sigma_i \qquad \sigma_{i+1} \sigma_i a_i = a_i \sigma_i$$

- Proof (beginning):
  - ▶ The relations (...) hold in  $B_\bullet$  (obvious);
  - ▶ For the other direction, introduce
    - $B_\circ :=$  the group presented by (...); we know  $B_\circ \twoheadrightarrow B_\bullet$ ; we want  $B_\circ \simeq B_\bullet$ .
    - $B_\circ^+ :=$  the monoid presented by (...).

- Fact: The group  $B_\circ$  is generated by  $\sigma_1, \sigma_2, a_1, a_2$ .

Example:  $\sigma_3 = a_1^{-1} \sigma_2 a_1 =$

- Main lemma: The monoid  $B_\circ^+$  is cancellative and admits least common multiples and greatest common divisors. It is a **Zappa-Szep** product of  $B_\infty^+$  and  $F^+$ .

$B_\infty^+ \times F^+$  with **two** actions:  $a_i \cdot \beta = db_i(\beta) \cdot a_{\beta^{-1}(i)}$   
 $F^+$  acts on  $B_\infty^+$  by doubling strands,  $B_\infty^+$  acts on  $F^+$  by permuting positions.

- Proposition: The group  $B_\circ$  is a group of fractions for the monoid  $B_\circ^+$ , and one has

$$B_\circ = (F^+)^{-1} \cdot B_\infty^+ \cdot F^+.$$

- ▶ Every parenthesized braid diagram can be isotoped to a diagram  
 “dilatation + braid + contraction”.

- Proposition: Let  $sh : \sigma_i \mapsto \sigma_{i+1}$  and  $a_i \mapsto a_{i+1}$  for every  $i$ . For  $g, h$  in  $B_\circ$ , let

$$g * h := g \cdot sh(h) \cdot \sigma_1 \cdot sh(h)^{-1},$$

$$g \circ h := g \cdot sh(h) \cdot a_1.$$

Then  $(B_\circ, *, \circ)$  is an *augmented LD-system*.

$$\begin{cases} x * (y * z) = (x * y) * (x * z): \text{self-distributivity, "LD"} \\ x * (y \circ z) = (x \circ y) * z \\ x * (y \circ z) = (x * y) \circ (x * z) \end{cases}$$

- Recall: want to prove  $B_\circ \simeq B_\bullet$ , i.e.,  $B_\bullet$  presented by the “braid-Thompson” relations  
(no other relation in  $B_\bullet$  than those of  $B_\circ$ )
  - Need to show that, for  $w$  a parenthesized braid word, the isotopy class of the diagram  $D(w)$  determines the class  $[w]$  of  $w$  in  $B_\circ$ .

- Proof (sketch):

- Use **diagram colorings**: Having fixed a set  $S$  with a binary operation  $*$ ,
  - put colors from  $S$  on the top ends of a (parenthesized) braid diagram,

- propagate using the rule
 

- works (compatible with Reidemeister move) when  $*$  obeys the **LD law**.

- Here: use  $B_\circ$  and its LD-operation  $*$  for coloring diagrams
  - the point: there exists **eval** :  $(B_\circ)^\infty \rightarrow B_\circ$  such that, in  $B_\circ$ ,

implies  $\text{eval}(\vec{x} \cdot D(w)) = \text{eval}(\vec{x}) \cdot [w]$ .

- hence,  $[w]$  recovered from the isotopy class of  $D(w)$ .

□

- Proposition: The augmented LD-system  $(B_\bullet, *, \circ)$  is *torsion-free*.  
↑  
every element of  $B_\bullet$  generates a free subsystem
- Proposition: Every element of  $B_\bullet$  has a canonical expression in terms of *special* ones.  
↑  
the closure of 1 under  $*$  and  $\circ$
- Proposition: The group  $B_\bullet$  is *orderable*; more precisely: every element of  $B_\bullet$  has an expression in which the  $\sigma_i$  with minimal index occurs positively only (no  $\sigma_i^{-1}$ ).  
▶ similar to  $B_\infty$ , but not expected because of the  $a_j$
- Proposition: The group  $B_\bullet$  is (isomorphic to) M. Brin's group  $\widehat{BV}$ .  
"braid group on one strand"

▶ a typical element:

Plan:

- 1. Artin's braid group  $B_\infty$
- 2. Thompson's group  $F$
- 3. The parenthesized braid group  $B_\bullet$
- 4. The Artin representation of  $B_\bullet$

- Recall:  $D_n =$  disk with  $n$  punctures
  - Here: **Cantor set** of punctures.
  - Technically more convenient to start with a **sphere** rather than with a disk.
- Definition:  $S_K :=$  sphere  $S^2$  with a Cantor set of punctures removed on the equator.
  - = two hemispheres connected by bridges indexed by **dyadic numbers**

- Fact:  $\pi_1(S_K)$  is a free group with a basis indexed by finite sequences of integers.

- Action of  $B_\bullet$  on  $S_K$  by homeomorphisms: an embedding of  $B_\bullet$  in  $\mathcal{MCG}(S_K)$

a “Dehn twist”  
exchanging  $D_i$  and  $D_{i+1}$

a “dilatation–contraction”  
expanding  $D_i$  and contracting  $D_{i+1}$

- Induces an action  $\rho$  on  $\pi_1(S_K)$  (“Artin representation”):

$$\blacktriangleright \text{read } \rho(\sigma_i): \begin{cases} X_{i,s} \mapsto X_i X_{i+1,s} X_i^{-1} \\ X_{i+1,s} \mapsto X_i \\ X_{k,s} \mapsto X_{k,s} \text{ for } k \neq i, i+1 \end{cases}$$

$$\rho(a_i): \begin{cases} X_i \mapsto X_i X_{i+1}, & X_{i,1,s} \mapsto X_{i,s} \\ X_{i,j+1,s} \mapsto X_{i+1,j,s} \text{ for } j \geq 2 \\ X_{k,s} \mapsto X_{k,s} \text{ for } k < i \\ X_{k,s} \mapsto X_{k+1,s} \text{ for } k > i \end{cases}$$

• Proposition: The Artin representation  $\rho$  of  $B_\bullet$  in  $\text{Aut}(F_\infty)$  is *faithful*.

• Proof:

▶ Uses the LD-structure again

▶ Method: Show that, if a braid word  $w$  contains one  $\sigma_1$  and no  $\sigma_1^{-1}$ , then  $\rho(w)$  moves some  $x_s$ , hence is nontrivial.

▶ Key point:  $\rho(w)$  can be read from colouring trees

(similar to the Hurwitz action of a braid word on a sequence)

▶ If  $w$  contains one  $\sigma_1$  and no  $\sigma_1^{-1}$ , then  $\rho(w)(x_1)$  finishes with  $x_1^{-1}$ , hence  $\rho(w)(x_1) \neq x_1$ , hence  $\rho(w) \neq \text{id}$ . □
